Add WeChat powcoder

# Recap

- Freelist-based allocators
- Bug elimination techniques:
  - Red zones
  - Poison values
  - Shadow memory
- Address Sanitizer

# Freelists and overflows

## Assignment Project Exam Help

- Attacker writes to a chunk
- Exploits a (small) buffer overflow to overwrite the header of the next chunk
- Causing inconsistencies
- Which can be exploited

<https://powcoder.com>

Add WeChat powcoder

# Securing the heap

- Canaries in metadata
  - Detects (some) overflows
- Moving metadata to the shadow memory
  - Prevents exploitation of heap structure
- Randomise allocation
  - Avoids deterministic layout
- Use *guard pages*
  - Catches buffer overflows

# Techniques – ASLR

Assignment Project Exam Help

<https://powcoder.com>

- Address Space Layout Randomisation
- Allocate segments of the process at random addresses
- The attacker does not know the virtual addresses of the data and code
  - But sometimes can learn it
  - Low entropy on 32 bit machines

# OS Memory Management

Assignment Project Exam Help

<https://powcoder.com>

- The virtual address space consists of fixed-size *pages*
- Pages map to physical *frames*
- Pages are associated with a *backing store*
  - Determines where contents is paged out to

# The mmap interface

- Associates a virtual address with a backing store
- Program execution
  - Associates code and data with binary file
- Heap and stack
  - Associate pages with the swap
- Shared libraries
- sbrk

Add WeChat powcoder

# Guard pages

Assignment Project Exam Help

- Non consecutive heap allocation

- Possibly at random addresses

<https://powcoder.com>

- Limits overflow length

Add WeChat powcoder

- No need to check for overflow

- ElectricFence

- Allocates one object per page.

# Techniques - BiBOP

- Big Bag of Pages
- Prevents exploitation (also used for performance)
- Dedicate a separate region of memory for each supported chunk size
- Use a separate directory to indicate which chunk is available
- Separates metadata from the malloc arena
  - Protects against metadata manipulation

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

# Techniques - randomisation

- Prevents exploitation – not good for debugging
- Address Space Layout randomization (ASLR) initialises the break at a random location.
- Randomise choice of chunk to allocate
  - Easy with BiBOP
  - Limited support with freelist

Add WeChat powcoder

# Diehard – idea

- Heap structure that solves all memory bugs
- Allocate chunks with infinite length red zones
- Never free/reuse memory
- Secure, but there is a slight problem...

# Diehard – realisation

Assignment Project Exam Help

<https://powcoder.com>

- Suppose we need  $M$  chunks
- Get space for  $\alpha M$  chunks, for some  $\alpha > 1$
- A bit-map of size  $\alpha M$  bits keeps track of free chunks.
- Allocation: pick a random free chunk – mark as used
- Free: mark as free
